DEVICE FOR LONGITUDINAL GUIDANCE OF A MOTOR VEHICLE BY  
INTERVENTION IN THE BRAKE SYSTEM

FIELD OF THE INVENTION

The present invention relates to a device for longitudinal  
guidance of a motor vehicle, having a driver assistance system  
which outputs a brake request signal to a brake control  
5 device.

BACKGROUND INFORMATION

One example of such a device is an ACC (Adaptive Cruise  
Control) system which makes it possible to adjust the velocity  
10 of a vehicle to the velocity of a preceding vehicle, located  
with the help of a radar system, so that the preceding vehicle  
is followed at a suitable safety distance. To do so, the  
driver assistance system intervenes in the drive system and,  
if necessary, also intervenes in the brake system of the  
15 vehicle. The intervention in the brake system has  
conventionally been accomplished by regulating the braking  
deceleration to a setpoint braking deceleration calculated by  
the driver assistance system. When this regulation takes place  
in the brake control unit, the setpoint braking deceleration  
20 forms the brake request signal which is output by the driver  
assistance system.

ACC systems in use today are generally designed for travel at  
a high velocity, e.g., on a highway. However, there are  
25 efforts to expand the function range of such systems to low  
velocities and in particular to include a stop-and-go function  
in which the vehicle is automatically brakable to a standstill  
when the preceding vehicle stops, e.g., in a traffic jam. The  
problem occurring then is that inaccuracies during measuring
